Abstract

A reappraisal of geothermal data of the mainland of Africa has been carried out based on data sets available at the IHFC website, incremented with updated information on volcanic activities of post Holocene times. Our compilation makes use of 1480 heat flow values that include 1327 observational data supplemented with 36 estimates derived from heat flow-age relation. In addition, the method of magmatic heat budget (MHB) has been employed in deriving deep crustal heat flow values for 117 for sites of recent volcanic activity, most of it located in Ethiopia. These data sets were regrouped into regular equal-area cells with dimensions of 5 x 5 degrees and subsequently employed in deriving maps of the regional distributions of heat flow and geothermal resources and interpreted on the basis of available information on tectonic setting and geological characteristics. The most prominent features are the relatively high values in the region of rift valleys in the eastern sector of the continent. High heat flow values also occur along north-south trending belts of Atlas Mountains in the north and pockets associated with the Cameroon volcanic chain on the west-central parts of the continent. The vertical distributions of temperatures were calculated for depths reaching down to 6 km. The associated resource base calculations indicate availability of high temperature resources in vast regions of the African continent.

1. Introduction

A number of regional geophysical studies have been carried in the continental segment of the African lithospheric plate, composed of cratons that formed during Archean times (about 3.6 to 2 billion years), fold belts of Precambrian age, sedimentary basins of Phanerozoic period and geological elements hosting a variety of rift and volcanic features of Cenozoic times. Results of such studies have been useful in understanding the general tectonic characteristics of the continent. However, because of the large area extent of these tectonic units, most of the earlier studies have been made as parts of regional investigations of limited extent that provide only segmented views of the regional geophysical fields. This has been a major obstacle in understanding structure of large-scale tectonic features and their interactions within the geodynamic framework. A prime example of such a situation may be found in geothermal studies of the continent, some of which has been carried out with focus on geothermal energy assessments. In this context, the main purpose of the present work is in providing a reanalysis of the results of geothermal measurements in the African continent and consider its implications for mapping largescale thermal features of the crustal segments.

For purposes of the present work we define African continent as the contiguous portion of the landmass lying roughly between Atlantic Ocean to the west, Mediterranean to the north, Red sea rift in the east and Indian ocean to the south. Excluded from this definition are the Sinai Peninsula in the east, islands in the Indian ocean (for example, Madagascar) and the relatively small islands in Atlantic Ocean to the west. It is obvious that this choice is based mainly on geographic considerations and do not follow political boundaries. The outline of the area considered is illustrated in the map of Figure 1.

2. Overview of Heat Flow Data for Africa

The surface thermal conditions of Africa are known to have a marked effect on subsurface temperatures at shallow depths. In the African continent there are considerable variations in the mean annual surface temperatures. In north-central Africa surface temperatures are high in the range of 25 to 30°C while much lower values prevail in the southern regions. The geographic distribution of mean annual surface temperatures for Africa has been discussed for example by New et al. (2000 and NOAA, 2019). But very little is known of the regional subsurface thermal conditions, which depend

on analysis of data on geothermal gradients derived from measurements in underground mines and boreholes. Needless to say, it also has significant impacts in the perspectives for utilization of geothermal resources at shallow depths.

The heat flow data sets employed in the present work is derived from the compilations carried out by the International Heat flow Commission – IHFC (Jessop et al., 1976, IHFC, 2013). Initial versions of IHFC data base have been employed in several studies of continental heat flow variations (see for example: Pollack et al., 1993; Davis and Davis, 2010; Gotourbe et al., 2011, Macgregor, 2019). However, very little attention has been paid in these earlier compilations for verifying the reliability of the values compiled in the IHFC data base. In many cases, crucial data on temperature gradient and thermal conductivity are missing. Also, unrepresentative and/or incorrect values of these parameters have been employed in calculation of heat flow values. In the present work, attention is focussed in verifying and proposing use of representative values for all sites of heat flow measurements reported in the IHFC data base for the African continent. In many cases, the absence of thermal conductivity or temperature gradient values were corrected based on well-known relations between heat flow, temperature gradients and thermal conductivity. Such corrections assume that steady state conditions prevail, that heat transport is mainly by conduction and that other disturbing processes (such as thermal refraction, topography and water flow) are absent. In some cases, literature values of representative thermal conductivity were employed. The corrections also took into account plausible geothermal characteristics of regional geologic and tectonic settings.

According to results of the present work heat flow measurements have been carried out in 32 of the 49 countries. The total number of data is 1327 and the mean heat flow is $55 \pm 20 \text{ mWm}^2$. The data density is approximately 0.2 per km^2 . The geographic distribution of the corrected data base is illustrated in the map of Figure 1. The crosses in this figure indicate central points of the grid system employed in deriving numerical representation of the heat flow field. A detailed list of heat flow values is given in Appendix – 1.

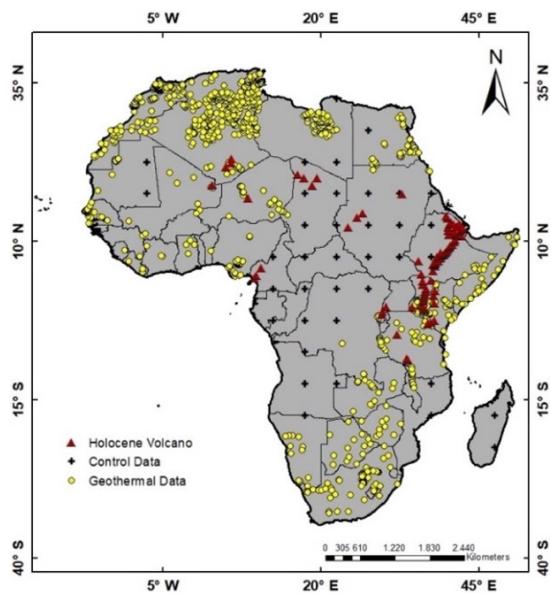

Figure 1 - Distribution of chosen heat flow data base for mainland Africa. Crosses indicate locations of cells in the grid system employed for deriving heat flow maps.

Presented in Table 1 are the number of heat flow values for 33 countries. Heat flow measurements have not so far been carried out in the remaining seventeen countries. The data density is expressed as numbers per 10^6 km^2 .

Total	1327	14.09×10^6	197156	55	20

Note that there are considerable variations in the data density. Most of the data are concentrated in the northern and southern parts of the continent. Data density is poor in the central parts of the continent. Algeria, Morocco and South Africa stand out as countries with more than 100 measurements. On the other hand, Benin, Chad, Cote d'Ivoire, Rwanda, Sierra Leone and Sudan have less than five values each. Heat flow in excess of 70 mW/m^2 were found in Algeria, Sudan, Tunisia and Western Sahara. Values of standard deviation in excess of 20 mW/m^2 have been found for Congo, Egypt, Kenya, Mozambique, Malawi and Sudan.

3. Influence of Tectonic Setting on Heat Flow

The main age provinces in mainland Africa (Arquean, Proterozoic, Paleozoic, Mesozoic and Cenozoic) have been considered as indicative of the tectonic setting of the continent, illustrated in the map of Figure 2. As can be verified in this map the northwestern and southern parts of the continent have higher predominance of Arquean and Proterozoic provinces, while the central and eastern provinces are characterized by provinces of younger age values. The dots in this map indicate locations of heat flow measurements reported in the IHFC data base.

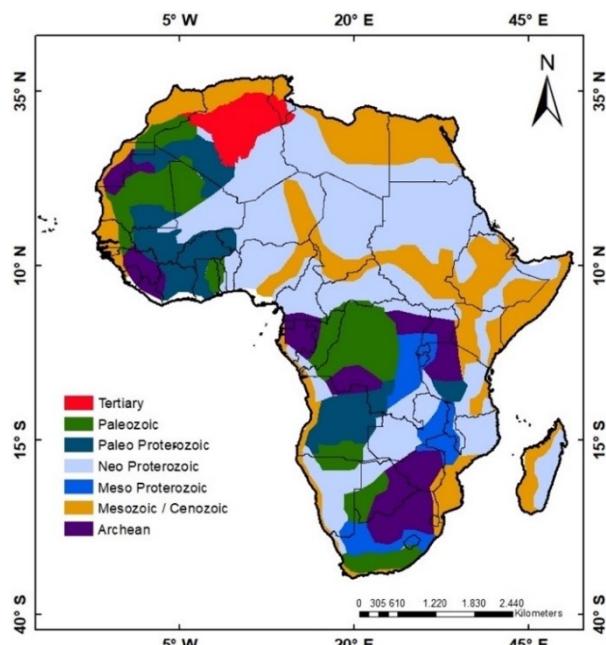

Figure 2 – Distribution of heat flow data relative to the tectonic provinces

Analysis of data reported in IHFC compilation indicate that Arquean provinces are characterized by relatively low heat flow values of less than 60 mW/m^2 , the average value being 50 mW/m^2 . For the vast periods of Paleo, Meso and Neo Proterozoic present heat flow is constant with values falling in the range of 55 to 65 mW/m^2 . Apparently, this trend has continued for age provinces described as Precambrian and Paleozoic. The value of present heat flow increases to 67 mW/m^2 for Mesozoic provinces. This is followed by another notable jump to 80 mW/m^2 for Tertiary provinces. In fact, the highest mean value of 82 mW/m^2 is encountered for localities in the Tertiary province. The distribution of data with respect to the tectonic provinces is illustrated in Table 2.

Table 2 - Heat flow values for tectonic provinces in Africa.

Age Province	N	Average	σ
Arquean	160	50	13.2
Paleo-Proterozoic	23	59	34.5
Meso-Proterozoic	77	59	38.7
Neo-Proterozoic	198	60	23.5
Precambrian	5	50	36.4
Paleozoic	45	59	24.4
Meso-Cenozoic	563	67	23.8
Tertiary	214	80	15.6
Total	1327	55	20

A similar trend can also be seen with respect to the geologic provinces, the details of which is provided in Table 3. The geologic province of Precambrian has heat flow of 51 mW/m^2 while for Jurassic provinces it is in the range of 71 to 76 , which is higher than that for Cenozoic and Tertiary.

Table 3 - Mean and standard deviation of heat flow for the geologic provinces in Africa.

Ages	N	Average	σ
Precambrian	227	51	17
Paleozoic	94	60	22
Jurassic	99	71	24
Cretaceous	158	76	20
Cenozoic	34	63	19
Tertiary	603	67	23
Lakes and Seas	110	60	37
Areas Outside	3	118	43
Total	1327		

The heat flow map derived on the basis of IHFC data base in which the numerical interpolations take into consideration the geographic distribution of tectonic provinces is presented in Figure 3. Standard mapping procedures adopted for this purpose included calculation of mean heat flow values for a regular grid system of 5×5 degrees. However, the fact that not all grid elements have observational data creates a problem in interpolation schemes employed for deriving maps. Thus, representative heat flow values derived from heat flow – age relations (Polyak and Smirnov, 1968; Hamza and Verma, 1969) were assigned for grid elements that did not have observational data.

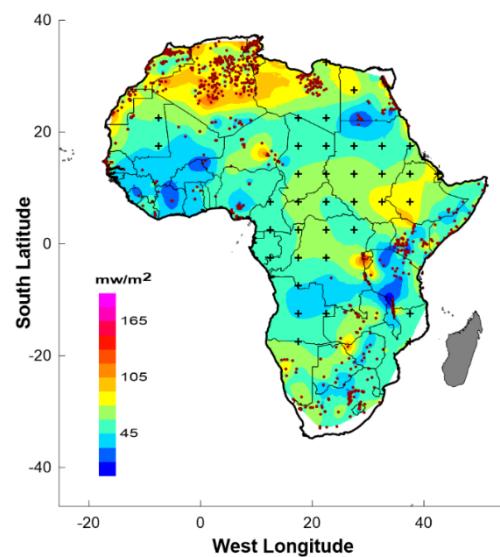

Figure 3 - Heat flow map of Africa taking into consideration influence of tectonic setting in numerical interpolation.

This map reveals relatively high heat flow in the northern parts of the continent but has failed to reproduce geographic extent of high heat flow fields of the East African Rift System. Also, there are no indications of high heat flow in the central and western parts of the continent.

4. Use of Heat Flow – Age Relations

In this some heat flow values in the central region of mainland Africa has been estimated using values derived from heat flow – age relations (Polyak and Smirnov, 1968; Hamza and Verma, 1969; Vieira and Hamza, 2011). Subsequently, these have assigned for grid elements that did not have observational data. In earlier works (see for example, Pollack et al, 1993) heat flow values obtained using an empirical form of this relation. In the more recent work of Vieira and Hamza (2011) heat flow values derived using the linear relation between heat flow and inverse of the square root of tectonic age. The equations used are derived from the general solutions observed in cooling of magmatic provinces (Carslaw and Jaeger, 1959 e Hamza, 1982). Under such circumstances, the relation between heat flow (q) and tectonic age of the last thermal event (t) can be written as:

$$q(t) = \alpha / \sqrt{t} + \beta \quad (1)$$

where α is the angular coefficient, β the intercept of the linear relation and t the elapse time since the last thermal event. The nature of the relation for the continent of Africa is illustrated in the upper panel of Figure 4. The lower panel illustrates the classical display of relation between heat flow and age on linear scales.

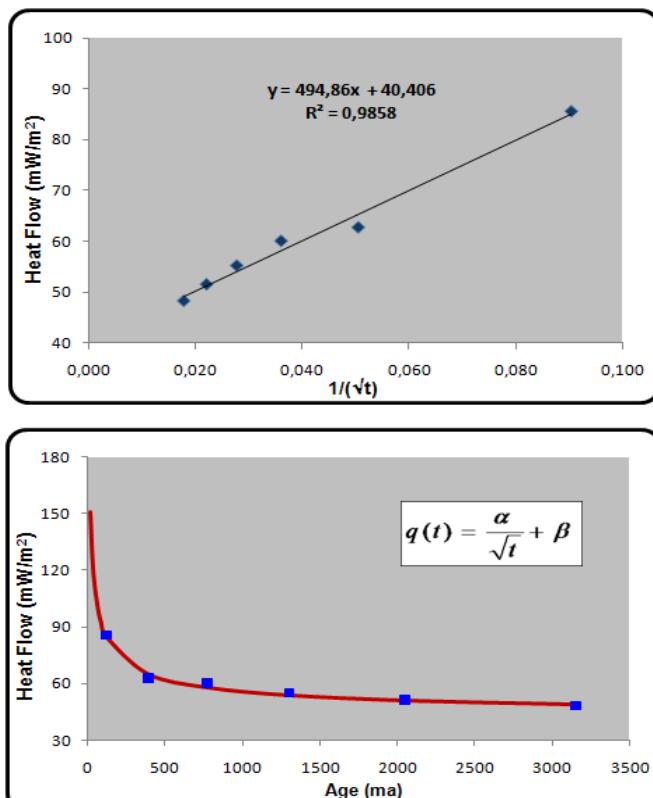

Figure 4 - Relations between heat flow and age of tectonic event for Africa. The upper and lower panels illustrate the inverse square root and linear dependences between heat flow and tectonic age.

Assigning heat flow values based on the heat flow – age relations allows derivation of synthetic global heat flow maps, as has been done by Vieira and Hamza (2011). Restricting the use of theoretical values only to areas where experimental data is unavailable has been widely an adopted practice (see for example Pollack et al, 1993). Figure 5 illustrates the results obtained for a data comprised of set of 44386 observational heat flow values supplemented with theoretical heat flow for areas without data.

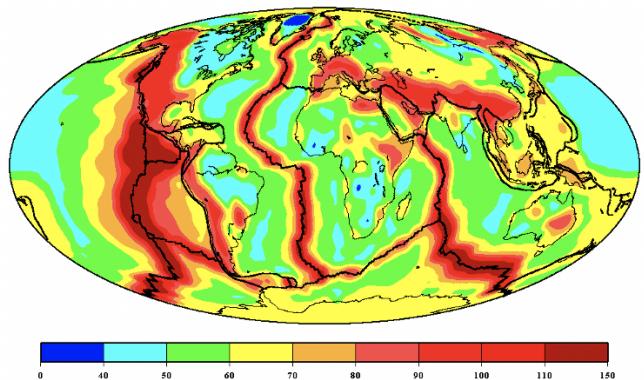

Figure 5 - Global heat flow map based on 44386 heat flow values supplemented with theoretical heat flow for areas without data (Vieira and Hamza, 2011)

5. Estimates of Heat Flow in areas of Volcanic Settings

According to available information volcanic activity plays a major role in the geothermal fields of the African continent. Clearly consideration of heat flux associated with volcanic activities is fundamental for better understanding of the crustal thermal conditions. However, for obvious reasons, heat flow measurements are rarely attempted in volcanic areas. Hence the need for considering a method that would allow for heat flow values in areas of volcanic regions. In this context we note the observations of Noguchi (1970) that the emplacement temperature of andesitic magma at mid crustal levels is approximately 1200°C while the depth of emplacement falls in the range of 15 to 25 km. Similar estimates were also made by Mamani et al. (2000), Annen et al. (2006), Suarez (2017), and Borzotta et al. (2018).

Smith and Shaw (1978) considered the relation between magma volume (in cubic kilometers) and time elapsed (in years) as approximately linear, when both are expressed on log scale. A combination of such observations can be employed in obtaining a rough estimate of heat flow for volcanic regions. The essence of this new procedure, designated as the method of Magmatic Heat Budget – MHB, has already been employed in obtaining estimates of heat flow in several regions of South America (Vieira and hamza, 2019) and Antarctica (Guimaraes et al., 2020). may be understood by considering the importance of residual heat in magma emplacement. In general, the quantity of residual heat is dependent on the magma volume emplaced and time elapsed after its emplacement. Our interest in the present context is in estimating heat flux for volcanic regions of Africa. The starting point is the relation between magma volume (in cubic kilometers) and time elapsed (in years) proposed by Smith and Shaw (1978). It is approximately linear, when both are expressed on log scale. An example of this line of reasoning is illustrated in Figure 6

where the domain limited by dashed line may be considered as representing the division between regions with and without residual magmatic heat.

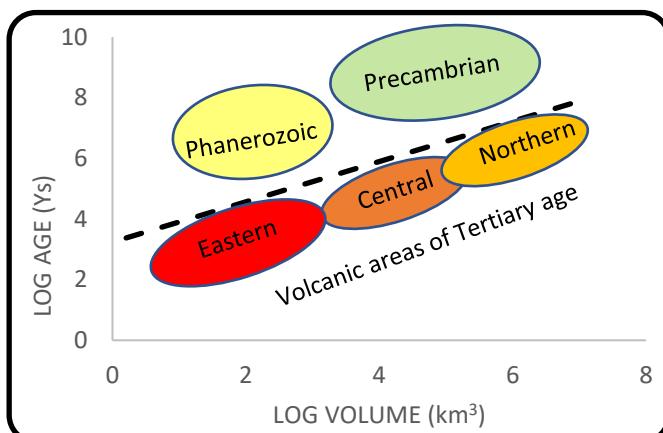

Figure 6 - Relation between volume and age for areas of volcanic activity (Adapted from Smith and Shaw, 1978).

In other words, sites falling in the region below the belt of dashed lines may be considered as having potential for retaining residual magmatic heat in subsurface layers. For the same reason, sites falling above the belt of dashed lines may be considered as those with little residual magmatic heat.

Clearly it is necessary to examine in some detail information on locations and age values of volcanic activities in the African continent. According to available information eruptions occurred in about 41 volcanic regions in about 10 countries during historic times. These have ages < 10000 years. Heat flow in such areas of recent volcanic areas estimated on the basis of MHB method is estimated to be in the range of 120 to 150mW/m². This list of volcanic areas is presented in Table 4.

The locations of volcanic regions listed in tables 4 and 5 are indicated in the map of Figure 7. Heat flow in such areas extinct volcanic activity is estimated to be in the range of 100 to 150mW/m². In this map the triangles in red color indicate locations of heat flow estimates for regions of volcanic activity.

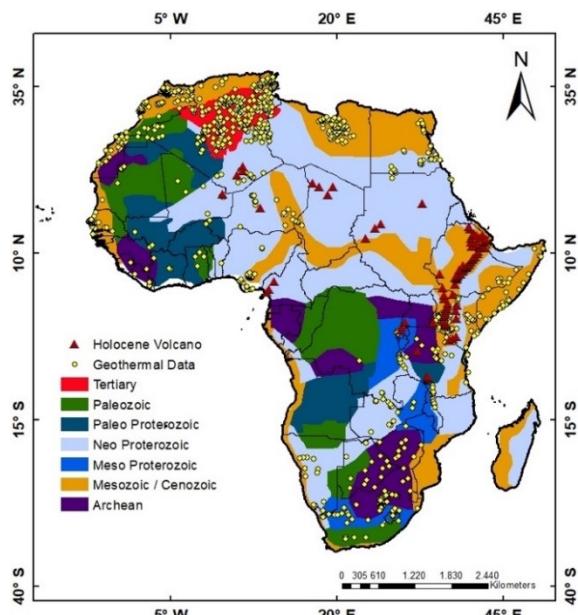

Figure 7 - Distribution of observational and estimated values of heat flow. The triangles in red color indicate sites of heat flow values estimated for locations of volcanic activities.

The heat flow map based on this data set is presented in Figure 8. Estimated values of heat flow were employed for 32 grid elements. It reveals relatively high values not only in the northern parts of the continent but also heat flow fields in locations of the East African Rift System. Also, there are indications of high heat flow in the central and western parts of the continent.

6. Crustal Temperatures

Data sets on heat flow and crustal structure provide basis for determining distributions of temperatures in the upper

crust. In view of the inherent uncertainties in such data sets, calculations are usually based on simple one-dimensional heat conduction models. These incorporate the effects of depth-dependent variations in thermal conductivity and radiogenic heat production. For layered media with constant thermal properties the relation for temperature (T_i) as a function of depth (z_i) is (Hamza, 1982):

$$T(z) = T_{0i} + \frac{q_{0i} - A_{0i} D_i^2}{\lambda_i} z + \frac{A_{0i} D_i^2}{\lambda_i} [1 - e^{-z_i/D_i}] \quad (1)$$

where T_{0i} is the surface temperature, q_{0i} the surface heat flux, A_{0i} radiogenic heat productivity and λ_i the thermal conductivity of the i^{th} element.

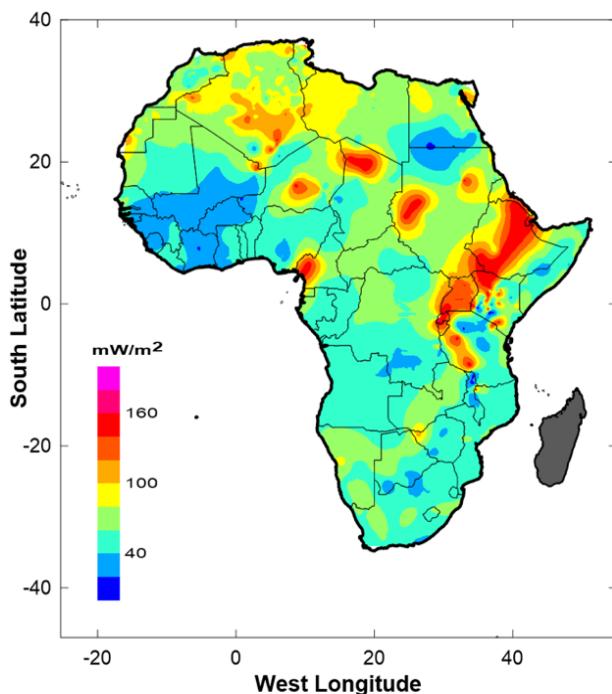

Figure 8 - Updated heat flow map of mainland Africa.

It is common practice to designate the difference between terms $T(z)$ and T_0 of equation (1) as the excess temperature (ΔT). The relation for excess temperature may be written as:

$$\Delta T = \frac{q_0}{k} d - \frac{A_{0rad} d^2}{2k} (1 - e^{-z/D}) \quad (2)$$

Following the usual practice in geothermal model studies, the value of A_0 is derived from empirical relations (Cermak et al., 1991) relating crustal seismic velocities with radiogenic heat productivity. This procedure has been adopted in the present work for calculating temperature distributions and in deriving maps of basal temperatures of the principal crustal layers. The model calculations were carried out for a set of thermal conductivity values representative of the main regional geological formations in the continent (Hamza et al., 2005; 2017). Such procedures introduce some degree of uncertainty in model results. However, the magnitudes of associated errors are likely to be less than inherent uncertainties in the gradient and heat flow values.

According to model results obtained in this work, excess temperatures in the range of 90 to 150°C occur in several localities at depths of one to three kilometers, in western and central parts of mainland Africa. These include the volcanic areas as well as regions of occurrences of hydrothermal activities. On the other hand, much lower temperatures occur

at similar depths along the northern and central parts of the continent. One of the convenient means of illustrating vertical distribution of excess temperatures is by using stacks of crustal temperature maps at conveniently chosen depth levels, which allow a three-dimensional perspective. Results of such an attempt is illustrated in Figure 9, for excess temperatures at depths of 3 to 6km.

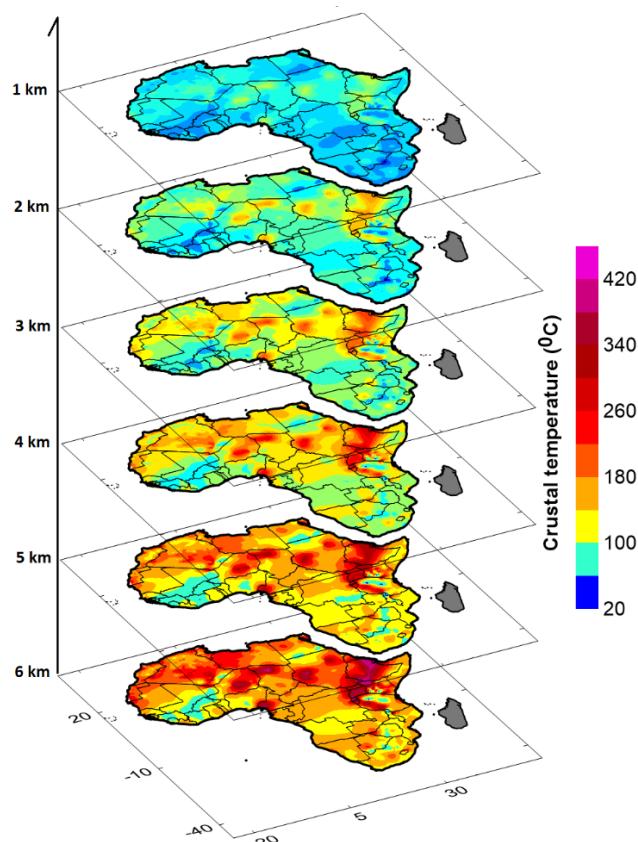

Figure 9 - Temperatures at depths of 1 to 6 km in mainland Africa.

Note that at depths less than 3km occurrences of geothermal systems with temperatures higher than 150°C are limited to areas of volcanic complexes in Ethiopia, Kenya, Cameroon and southern parts of Algeria. The possibility that crustal blocks with temperatures higher than 150°C, can be encountered at depths less than 3 km is important for planning exploration of Hot Dry Rock (HDR) and Hot Wet Rock (HWR) systems in these regions.

At larger depths of more than 4km, other high temperature systems appear along vast areas in the central parts of mainland Africa, stretching from Ethiopia to southern parts of Algeria and Morocco. The maps in the lower parts of Figure 6 illustrate the distribution of temperatures at the depth range of 5 to 6km. Note that in these cases occurrences of geothermal systems with temperatures higher than 150°C are not limited to the volcanic areas. Significantly large high temperature targets occur not only to the western sectors but also spread out to wide regions in the central stable platform areas.

7. Conclusions

A reappraisal of geothermal data of the mainland of Africa has been carried out based on data sets available at the IHFC website, incremented with updated information on volcanic activities of post Holocene times. Our compilation makes use

of 1480 heat flow values that include 1327 observational data supplemented with values derived for 117 sites of volcanic activities and 36 estimates derived from heat flow-age relation. These data sets were regrouped into regular equal-area cells with dimensions of 5 x 5 degrees and subsequently employed in deriving maps of the regional distributions of heat flow and geothermal resources and interpreted on the basis of available information on tectonic setting and geological characteristics. The most prominent features are the relatively high values of surface heat flow covering much areas of Ethiopia and Kenya in the east-central sector of the continent. High heat flow values also occur along north-south trending belts of Atlas Mountains in the north and pockets associated with the Cameroon volcanic chain on the west-central parts of the continent. The vertical distributions of temperatures were calculated for depths reaching down to 6 km. The associated resource base calculations indicate availability of high temperature resources in vast regions of the African continent at depths greater than 3 km. High temperature resources also occur in several isolated regions in the central and northern regions.

8. Acknowledgments

The first author is professor at the Institute of Science Engineering and Technology, of the Federal University of Jequitinhonha and Mucuri Valleys, Teófilo Otoni, Brazil. The second author is Coordinator of the Department of Geophysics of the National Observatory (ON/MCTI) at Rio de Janeiro. The third author of this work is recipient of a research scholarship (Process No. 306755/2017-3) granted by the National Research Council of Brazil (CNPq).

Appendix

*Summary of Heat flow data employed in this work, based on modified IHFC data compilation.
In many cases, representative values were adopted for geothermal gradient, thermal conductivity and heat flow.*

The abbreviations used in the main table of the Appendix are listed below.

Name	Description
ID	Data Identification Code. First three letters indicate abbreviation for country
Site	Name or Identification for Site
LON.	Geographic Longitude
LAT	Geographic latitude
EL	Elevation (m)
min D	Minimum Depth for temperature data (m)
max D	Minimum Depth for temperature data (m)
NT	Number of Temperature measurements
RG	Representative value of temperature gradient (oC/km). For details see text.
NK	Number of thermal conductivity data
RK	Representative thermal conductivity (W/m K). For details see text
NHP	Number of radiogenic heat production values
RHP	Representative radiogenic heat production ($\mu\text{W}/\text{m}^3$). For details see text
RQ	Representative heat flow (mW/m^2)
NS	Number of Sites
Publication	Brief list of references for primary publication. For details see IHFC compilation.
